16. Abstract

Volumes II and III of this document summarize the Phase II research results of the measured experimental data generated to document twelve full-scale staged collisions. Volume II presents results for staged collisions No. 1 through No. 5 and outlines test plans and procedures used to document the events. The objective of the staged collisions was to develop a library of experimental data which could be used to validate accident reconstruction techniques such as SMAC and CRASH. The test matrix focused on data gaps identified in Phase I (Volume I) involving intermediate and subcompact size vehicles. Collision configurations include frontal, side and rear impacts with both cars moving at velocities up to 40 mph. The vehicle measured parameters including vehicle compartment accelerations (X,Y,Z components) angular yaw velocity, compartment pitch, roll and yaw angle, wheel angular velocities, steer angle and vehicle trajectory. Each collision was photographically covered with ten high speed 16 mm data cameras. Occupant injury criteria data were obtained on the driver and front seat passenger in the target vehicle (V2), according to FMVSS 208 requirements.

FOREWORD

This document summarizes the research achieved under Contract No. DOT-HS-7-01511, "Research Input for Computer Simulation of Automobile Collisions", with National Highway Traffic Safety Administration, U. S. Department of Transportation. Volume I summarizes previous existing experimental data from staged collisions and presents plans for future data needs. The experimental data generated in twelve staged collisions are reported in Volumes II and III of this document. Volume II contains the experimental test data for Test No. 1 through No. 5. Volume III contains the test data for Test No. 6 through No. 12. The reconstruction of these collisions, using the CRASH and SMAC simulation programs, is reported in Volume IV of this document.

The Contract Technical Manager for Phase II was Mr. Thomas Noga of the National Highway Traffic Safety Administration.

The opinions and findings expressed in this publication are those of the authors and not necessarily those of the National Highway Traffic Safety Administration.

1.0 INTRODUCTION

Volumes II, III and IV contain the Phase II research effort conducted by Calspan Corporation entitled "Research Input for Computer Simulation of Automobile Collisions" (RICSAC) for the National Highway Traffic Administration (NHTSA) under Contract No. DOT-HS-7-01511. The objective of this research is to further evaluate the validity and accuracy of both the Simulation Model of Automobile Collision (SMAC) and the Calspan Reconstruction of Accident Speeds on the Highway (CRASH) computer programs. These two computer programs have been developed for the purpose of achieving uniformity in the method of reconstruction and interpretation of the physical evidence in automobile accidents.

The Phase I of this research program, which is reported in Volume I of this document, summarizes the results of a detailed review of existing experimental data from staged collisions which had been previously documented and presents plans to meet future data needs in relation to computer simulations for reconstructing highway accidents.

The Phase II part of this program involved the staging and documentation of twelve car-to-car collisions at Calspan's Vehicle Experimental Research Facility (VERF). The staged collisions were performed on a 400 foot diameter level asphalt surface with an average dry skid resistance value of 87.

The objective of the staged collisions in Phase II was to generate a body of fully documented collisions which can be used to test reconstruction techniques such as SMAC and CRASH and serve as training aids for accident investigators. The test plan for Phase II was focused on data gaps identified in Phase I and on accident types that have high occurrence rates.

2.0 TEST PLAN

In view of the program limitation to twelve staged collisions, it was necessary to choose a test matrix between (1) achieving single severity test

results for a variety of vehicle size combinations or (2) obtaining response data in similar impact configurations for more than one value of speed-change, ΔV. The latter choice was selected as being more productive for achieving meaningful measures of the accuracy of reconstructions. In recognition of the current trend toward smaller vehicle sizes, the test program contained intermediate and subcompact categories.

The twelve collision matrix contained two categories of vehicle sizes, five impact configurations and two values of ΔV for each impact configuration. Each staged collision involved an intermediate and a subcompact size vehicle except for one test in which two intermediate vehicles were selected.

To insure the staged collisions are representative of real life accidents both vehicles were in motion at impact except for the rear impact configuration in which the struck vehicle was stationary.

The test matrix for the 12 staged collisions is presented in Table 2-1 and the five impact configurations are shown in Figure 2-1.

Based on the findings of the Phase I Final Report, presented in Volume I, "Research Input for Computer Simulation of Automobile Collisions," a test matrix was selected for the twelve Phase II staged collisions. The test matrix in Table 2-1 contains two of the most representative models of the categories of vehicle sizes, subcompact and intermediate. The impact conditions are defined by impact velocity, heading angle and vehicle contact point. All vehicles were 1974 models or newer.

2.1 Selection of Vehicle Speeds

The detailed selection of vehicle speeds was based on SMAC runs that were performed prior to each staged collision with the goal of achieving ΔV values for the struck vehicle of approximately 15 mph and 30 mph for the two exposures in each collision configuration. The objective of the two severity

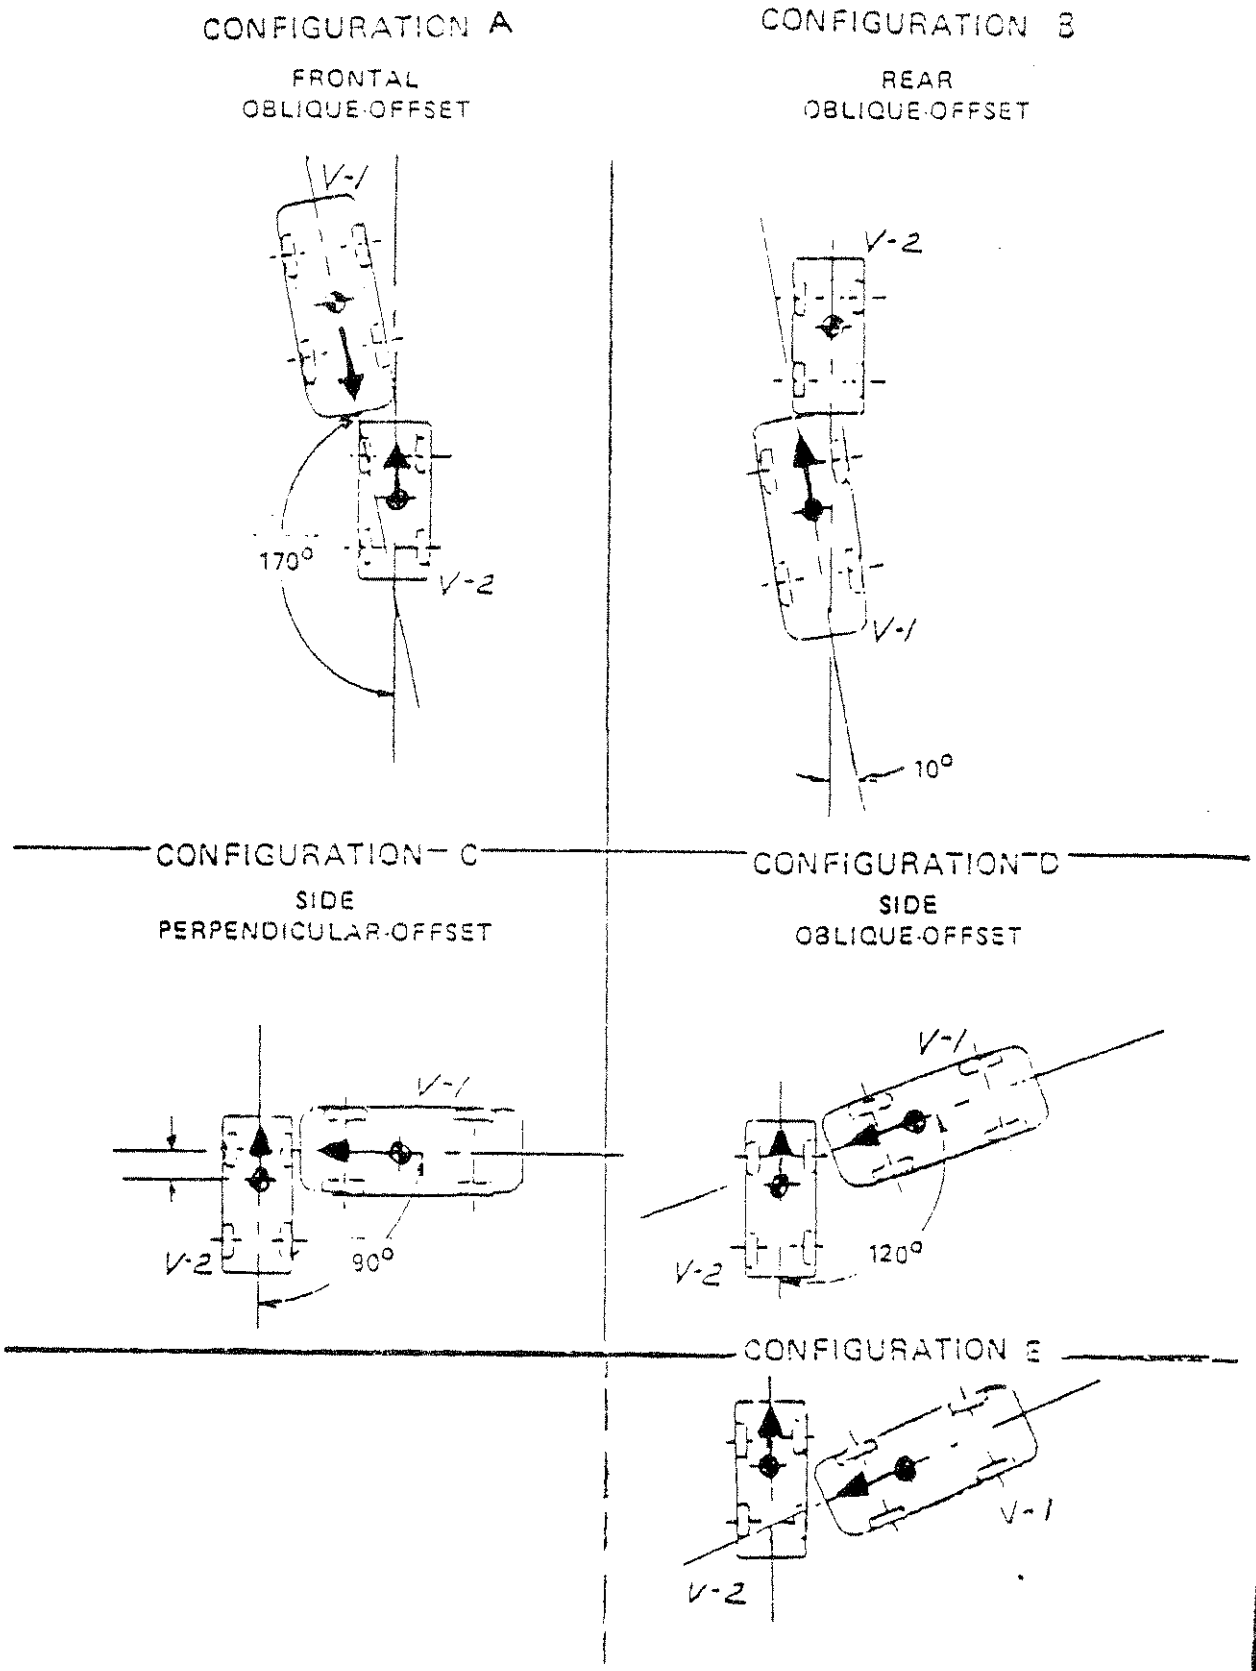

Figure 2-1 CAR-TO-CAR COLLISION CONFIGURATIONS

levels is to provide a basis for evaluating reconstruction accuracies over the ΔV range likely to be encountered in applications. For example, in side impact cases, data presented in Reference 2 indicate that approximately 90% of the struck vehicles in the MDAI files experience speed change of 30 mph or less and, further, that approximately 13% of the struck vehicles experience speed changes of 10 mph or less. Obviously, a realistic evaluation of application accuracies for such cases must include consideration of the indicated severity range.

2.2 Configuration Selections

A number of accident studies have included investigations of the distribution of collision configurations (e.g., Reference 3). In all such studies, frontal exposures have been found to rank first and side exposures second.

In view of the substantial representation of frontal collisions in the staged-collision data assembled in Reference 1, and of the fact that most collision configurations produce at least one frontal exposure, the selections include seven side impacts, two frontal and three rear enders. The two frontals were offset and oblique with the objective of producing both partial frontal contacts and yaw rotations during the spinout trajectories to permit testing of the corresponding aspects of reconstruction calculations.

Before conducting the scheduled staged collision, Calspan conducted a demonstrational test with two older vehicles to check out our recently improved towing and release system for oblique collisions with both vehicles in motion. Two cameras documented the performance of the towing and release mechanism of the towed vehicles.

3.0 VEHICLE INSTRUMENTATION AND PHOTOGRAPHIC COVERAGE

3.1 Vehicle Instrumentation

The selection and location of the vehicle instrumentation was based on the objective of generating experimental data in support of continued updating

and verification of the SMAC and CRASH computer programs. The instrumentation outlined for this program was selected with the objective of defining a minimum instrumentation package for use in future staged collisions related to accident reconstruction.

The vehicle parameters selected for documentation included the following items for each vehicle:

1. Acceleration - Three Components (XYZ)
2. Linear Velocity
3. Angular Velocity (Yaw)
4. Sprung Mass Pitch, Roll and Yaw Angle
5. Wheel Angular Velocities (RPM)
6. Wheel Steer Angle
7. Vehicle Trajectory During Contact and Spinout
8. NHTSA Crash Recorder

The selected standard vehicle instrumentation package is outlined in Table 3-1.

A minimum of 13 accelerometers were mounted on-board each vehicle to record acceleration components at six to seven stations on each vehicle as outlined in Table 3-1. At three locations triaxial (XYZ) packages were installed in each vehicle. These locations provide acceleration data at several locations between the front and the rear of the vehicle. All accelerometers were "hard mounted" to the vehicle structure.

The front wheel steer angle time history was measured on each vehicle by using a linear stroke potentiometer attached to the vehicle steering linkage. The output was calibrated in terms of wheel steer angle. The steer angle data

provide information needed to analyze vehicle trajectories during and after spinout.

Three or four wheel angular velocities were measured on each vehicle. No attempt was made to measure the wheel in direct contact with the striking vehicle because of the high probability of the transducer's destruction during the impact. The individual wheel rotation (rpm) time history was measured with an electrical tachometer driven by the angular rotation of the wheel. A flexible speedometer cable attached to the wheel hub was used to drive the tachometer mounted inside the vehicle. The flexible drive accommodates wheel steer angle and suspension deflection. Each tachometer was calibrated using a synchronous motor drive unit. This data provides direct measurements of the extent of individual wheel lock-up and braking action which occurs before and during the spinout phase of the collision.

The time history of the change in vehicle yaw, pitch and roll angles and yaw rate were recorded in both the bullet and target vehicles. A pair of two-degree-of-freedom, free gyroscopes and a rate gyro were mounted to measure the sprung mass attitude change of the vehicle axes with respect to a space-fixed reference axis system. The gyros, together with the solid state operational amplifiers were contained in a compact package capable of operating under an impact environment of over 40 g's.

Special attention was given to their orientation so as to minimize "contamination" of the signals due to cross-coupling effects of combined motions. One gyro was used in a vertical mode (spin axis parallel to vehicle vertical or Z axis) with the inner gimbal (axis athwartwise)measuring pitching and the outer gimbal measuring roll motions. The other gyro has its spin axis aligned parallel to the longitudinal axis of the vehicle for measuring heading angle. With the gyros so oriented, the gimbal pickoff signals are direct measurements of the angular coordinates of the sprung mass relative to the space-fixed axis system, except for yaw. The "contamination" of the yaw signal is considered minor because of the small magnitudes of the pitching and

rolling motions.

Vehicle Trajectory Marker

One of the more important data items requiring special attention was the documentation of the vehicle trajectories during vehicle interaction and spinout. The more traditional method to record the vehicle trajectory has been the use of several high-speed motion picture cameras located overhead on towers with supporting ground cameras at eye level height. To cover the complete event where major spinout occurs (in different directions) requires a rather large battery of cameras with overlapping field of views. Using several cameras to record the vehicle trajectory requires major effort in film analysis to establish a true trajectory. Parralax corrections within the field of view are a major concern requiring special procedures to minimize this error before an X-Y plot of trajectories can be obtained.

Based on the limitations and problems associated with the camera method for obtaining trajectories, Calspan designed and fabricated a special vehicle trajectory marker which proved to be a more direct method requiring considerably less effort in data analysis to obtain the desired X-Y plots. This method sprayed a liquid from the vehicle on to the surface leaving a trail to identify the path of the vehicle at two locations on the vehicle. To achieve this we used the airless paint gun principle, where high pressure air drives the fluid at high velocity from the nozzle without mixing with the fluid. We positioned the spray nozzle near the in-board side of the tire approximately 1 inch from the roadway. The two nozzles were attached to the unsprung structure of the vehicle so that suspension deflections would not change the elevation or location of the nozzle end. The liquid (colored water) under high pressure contacted the roadway surface in milliseconds after leaving the nozzle end.

The location and small quantity of water paint on the roadway did not affect the roadway coefficient of friction. We installed two nozzles on each vehicle, one at the front and rear wheels to define the complete vehicle trajectory. The operation of the trajectory marker was controlled by a solenoid

valve actuated by a contact switch before impact.

Crash Recorder - NHTSA

All vehicles except in Test 1 were equipped with a Teledyne Geotech Crash Recorder furnished by NHTSA. Table 3-2 lists the serial numbers of the crash recorder used in the vehicles on the respective tests. The recorders were installed under the front seat. Data from the on-board recorder can be correlated with the experimental test and the simulation results.

All recorders have been forwarded to NHTSA for their analysis.

Vehicle Data Reduction

The outputs from the transducers mounted on the vehicles are fed to signal conditioning and amplification equipment also mounted on-board. The amplified signals are then carried from the vehicles to remote recording station via a multi-channel umbilical cable and recorded on 14 channel FM tape recorders All the data recorded on this analogue tape is then converted to a digital output using a digital data reduction system. This system also has a number of software options which may be selected to obtain velocity and displacement by integration of the accelerations and to provide plots of all three parameters as a function of time. The measured accelerations (X,Y,Z) of each location were integrated to obtain velocity and displacement data. For the application of these data, See Section 1.0 in Volume IV of this document.

In addition to the time-history data from each transducer, the following crash test performance data was computer processed on selected channels and included in this report.

1. Vehicle Acceleration Time Histories
2. Vehicle Velocity Time Histories
3. Vehicle Displacement Time Histories
4. Triaxial Acceleration Resultant Time Histories
5. Vehicle Acceleration VS Displacements

3.2 Photographic Coverage

Still Photographs

The following are typical pre-test photographs obtained using a standard press camera (4" x 5" negative) with black and white film.

1. Side view - both sides, both cars.
2. Front view - both cars.
3. Rear view - both cars.
4. Interior view to show dummy positioning (both sides).
5. On-board instrumentation packages.
6. Selected views of transducers.
7. Underside - both cars.
8. Overall test site viewed from camera tower.

Likewise, the following post-test photographs were obtained using a standard press camera (4" x 5" negative) with black and white film.

1. Side view - both sides, both cars.
2. Front view - both cars.
3. Rear view - both cars.
4. Right front three-quarter view - both cars.
5. Left front three-quarter view - both cars.
6. Right rear three-quarter view - both cars.
7. Left rear three-quarter view - both cars.
8. Interior view showing post-test dummy positions (both sides).
9. Underside - both cars.
10. Selected views showing details of vehicle damage
11. Overall test site viewed from camera tower showing vehicle positions.
12. Overall test site viewed perpendicular to test track showing vehicle positions.
13. Overall test site viewed parallel to test track showing vehicle positions.

High Speed Photography

A minimum of 10 high speed data cameras (16 mm) were used to photograph the event for each test. Cameras were stationed on the ground at eye level elevation and cameras were located on portable towers. All 16 mm data cameras used color film.

All high speed cameras were controlled by timing equipment in Calspan's photo-instrumentation control van. This control unit provides overall control of camera-event sychronization and time coding of film.

Vehicle impact time (time = 0) was established by a common photoflash which was recorded by all data cameras. The time zero event was actuated by a pressure contact switch positioned on the contact surface of one of the vehicles. This same event mark was coded electronically on all data recording equipment.

Since the spinout phase of the collision does not require the detailed analysis that the actual collision phase requires, i.e., the 1000 fps coverage is needed to adequately define the transient collision interface, the cameras filming the spinout ran at approximately 400 fps. Note that this is consistent with the usual practice in running the SMAC simulation program where a 5 ms time interval specified for the pre-collision and spinout phases is reduced to a 1 ms interval for the collision phase.

Documentary Photography

Two 16 mm motion picture cameras (24 fps) provided the following minimum coverage of the test.

- Pre-test vehicle conditions including instrumentation, dummy positions and vehicle details.
- Planning scenes, tracking vehicles before, during and after impact (one camera on each vehicle).
- Post-test vehicle conditions including damaged areas, dummy positions and special details of interest.

3.3 Dummies - Part 572

Two anthropomorphic Part 572 test dummies (50 percentile male) furnished by NHTSA were positioned in the front seat of both vehicles. For indications of dummy contact areas within the compartment, colored chalk was applied to the dummies using a different color for each dummy. The two dummies in the bullet car (V-1) were restrained with the vehicle-equipped seat belt systems and they were uninstrumented in this program except for Tests Nos. 11 and 12.

The establishment of occupant injury criteria data was not considered a major obective of this research program; therefore, fully instrumented Part 572 test dummies were only provided in the target vehicle (V-2). Except for the two front-to-front collisions (Test 11 & 12), all the dummies in the target vehicle (V-2) were unrestrained. All the occupant injury data measurements and on-board camera coverage were sponsored by the Occupant Packaging Branch of NHTSA, on a piggyback arrangement with the present program.

Dummy instrumentation included the following channels of data:

1.	Head Acceleration	-	XYZ
2.	Chest Acceleration	-	XYZ
3.	Pelvic Acceleration	-	Y
4.	Femur Loads	-	L & R

The direction of the dummy velocity vector within the vehicle during the collision is important in accident reconstruction. The basic dummy trajectories were documented with a minimum of two on-board data cameras in each target vehicle. The on-board cameras were mounted on the outside door panels with a special lightweight bracket, the rear deck behind the rear seat and on the roof. This on-board camera coverage recorded dummy kinematics, general seat belt and seat performance, and compartment interior areas associated with dummy contacts. The on-board cameras operate at a nominal 1,000 frames per second.

The vehicle interior (excluding glazing) was sprayed with a coat of white latex paint as a means to improve photographic coverage of the dummies. A coating of dyed chalk solution was applied to interior surfaces which are likely to be contacted by occupant head and chest segments. Such surfaces included the instrument panel, windshield header, lower dash panel (knee bar), and steering control. Some compartment interior lighting using long duration flash bulbs was provided to improve on-board photographic coverage. The dummies were thoroughly inspected after each crash and refurbished as necessary in accordance with standard procedures.

4.0 VEHICLE AND TEST SITE PREPARATION

The following vehicle and site preparations were completed before the vehicles were transported to the test site:

4.1 Vehicle Inspection

A receiving inspection of all test vehicles was performed to determine the status and condition of the following items.

- Exterior panels
- Frame and suspension structure
- Door hinges and latches
- Steering column and dash panel
- Glazing
- Steering control and linkages
- Brake system
- Fuel system components
- Seats and seat anchorages
- Restraint systems
- Fuel tanks were drained and half-filled with stoddard solvent to simulate on-board fuel.

The vehicle towing and guide rollers assembly were attached to a suitable structure under the front of the vehicle.

Each test vehicle was checked before conducting the test to demonstrate proper tracking (wheel alignment) of the vehicle when under tow.

4.2 Photographic Markings, Dimensions

Two spherical targets were mounted on the roof of each vehicle to aid analysis of the overhead film coverage; this technique has proven very successful where x, y and angular displacements are to be measured from a film analysis. Each vehicle had contrasting colors for ease of analysis and grids were placed on the vehicles using checkered tape of 1 inch gradations positioned to help delineate the collision interface between the two vehicles. Typical vehicle markings and targets for photographic analysis are shown in Figure 4-1.

4.3 Vehicle Test Weight

The test weight of each vehicle was obtained by placing vehicle scales under each wheel. The vehicle longitudinal center of gravity was calculated from these weights. All tires were inflated to manufacturer's specifications. Ride height and weight of each wheel was measured with all equipment and dummies on-board.

4.4 Vehicle Test Preparation

The following vehicle preparation items were performed on all test vehicles:

1. Drain fuel tank and add approximately one-half tank of water colored with red dye.
2. Drain radiator and battery and fill with water.
3. Drain all oil base liquids except power steering fluid.
4. Assure all original equipment and accessories remain in vehicle.
5. Install specified instrumentation.
6. Install specified on-board camera system including interior photographic lights.

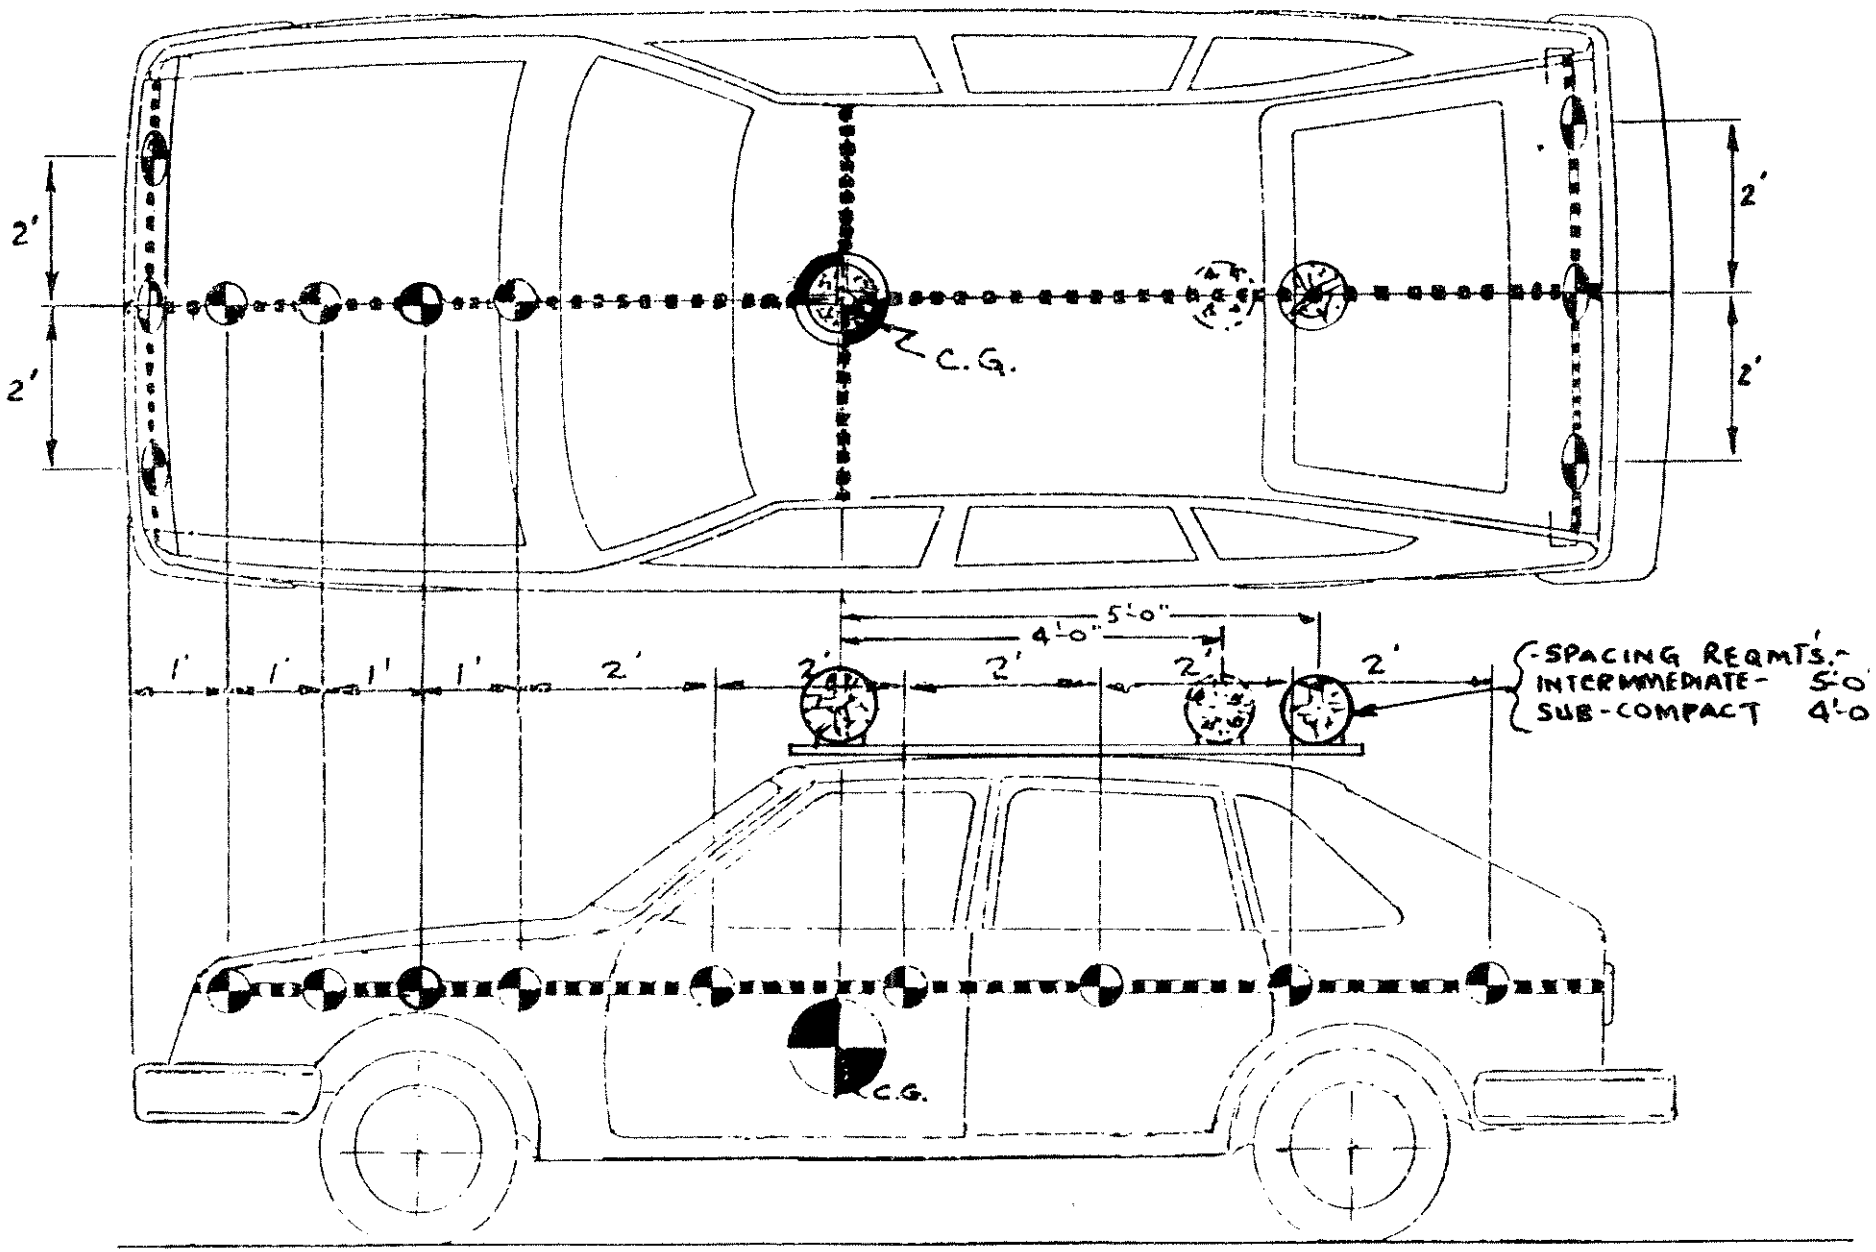

Figure 4-1 VEHICLE MARKINGS FOR PHOTOGRAPHY

7. Install on-board vehicle braking package.

8. Paint vehicle interior flat white for improved on-board photographic coverage.

9. Paint rotational marker on all four wheels.

10. Stencil test number and project identification number on both sides and roof of vehicle.

11. Secure vehicle photographic targets and checkered tape.

12. Install zero time impact flash system.

13. Position two dummies (Part 572, 50%) in the front seat and secure seat belt system per FMVSS No. 208 specifications when applicable.

14. Coat the steering wheel assembly, instrument panel, knee contact panel, windshield and door frame header with contrasting dyed chalk solution.

15. Inflate all tires to manufacturer's specified air pressure.

16. Install instrumentation and camera umbilical cable fixture.

17. Install towing and guidance hardware.

18. Weigh and ballast vehicle to the required weight after all equipment and dummies are on board.

19. Calculate vehicle center of gravity and c.g. targets.

20. Install spherical roof target fixture with the forward sphere on the vehicle c.g. station.

4.5 Test Site Preparation

The following test site preparation items were performed:

1. Layout and secure guidance rail system for specified collision configuration.

2. Locate and check pull cable pulleys required for specified collision.

3. Clean roadway surface at impact and spinout area.

4. Lay out Cable Tow System.

5. Position overhead camera towers and record location.

6. Locate ground camera stations and record location.

7. Locate stadium poles and ground markers and record location.

8. Secure pull cable release block for both vehicles.

9. Locate two timing clocks (50 msec/rev.) for maximum camera coverage.

10. Locate additional ground based zero time flash units for field of view by all data cameras.

11. Position speed trap for recording striking vehicle impact velocity.

4.6 Recording The Scene Data

To insure that each staged collision is documented thoroughly, the scene was investigated by Calspan's professional accident investigators. The following items were measured and the standard Collision Performance and Injury Report Form were completed by Calspan investigators.

1. Pre-impact skid marks or scuff marks for each wheel position - both vehicles.

2. At-impact position of each wheel - both vehicles.

3. Point of impact.

4. Final rest position of each wheel - both vehicles.

5. Gouges and scratches in the pavement surfaces.

6. Liquid spills and run-offs.

7. Debris, including directional dispersal.

8. Skid marks, scuff marks, etc.

9. Vehicle trajectory (paint trail).

The following scene data are presented in this final report for each test:

1. Accident schematic

2. Vehicle crush schematics L, C and D dimensions plus vehicle damage rating (CDC).

3. Scene and vehicle photographs (35 mm colored slides).
(Slides available under separate document.)

4. Occupant contact data.

5.0 Staged Collisions Test Data

All the experimental test data and supporting information for the twelve staged collisions is published in two volumes in this document. In addition, two copies of the edited 16 mm colored motion picture film coverage and 35 mm colored slides for each staged collision were transmitted to NHTSA to support the documentation of these experimental tests.

The following information and data for each staged collision is presented in this document:

7.0 RICSAC STAGED COLLISION - TEST NO. 1

EXPERIMENTAL RESULTS

Test Description

This staged collision involved a 1974 Chevrolet Chevelle Malibu (V-1) striking a 1974 Ford Pinto (V-2) on the right side (front section) at an oblique angle of 60 degrees as shown in Figure 7-1. The impact velocity of both vehicles was 19.8 mph. The vehicle test weights were 4460 and 3110 pounds for the Chevelle and Pinto, respectively. Each vehicle had two Part 572 test dummies (50 percentile) seated in the front seat. The dummies in the Pinto were instrumented according to FMVSS 208 and were unrestrained. In the Chevelle the dummies were uninstrumented and were restrained with seat belts.

The Chevelle was equipped with automatic transmission, power steering and power brakes. The Pinto had manual transmission, steering and standard brakes. The accident was staged with both transmissions in drive position, brakes off and the engines not running. During the collision no steering control inputs or vehicle braking was applied. The roadway was dry with skid resistance value of 87.

Approximately one car length before impact the vehicle tow cable was released and the vehicle guide rail was terminated. At this point in time and during the collision both vehicles are free bodies with no constraints except the normal collision forces and reactions encountered in this type of car-to-car collision. During the collision event no observed tow cable or instrumentation cable interference with the moving vehicles was noted.

TEST NO. 2

RICSAC STAGED COLLISION

FRONT-TO-SIDE
OBLIQUE - OFFSET

CHEVELLE/PINTO

VELOCITY 31.5 MPH

8.0 RICSAC STAGED COLLISION - TEST NO. 2

EXPERIMENTAL RESULTS

Test Description

This staged collision involved a 1974 Chevrolet Chevelle Malibu (V-1) striking a 1974 Ford Pinto (V-2) on the right side (front section) at an oblique angle of 60 degrees as shown in Figure 8-1. The impact velocity of both vehicles was 31.5 mph. The vehicle test weights were 4710 and 3260 pounds for the Chevelle and Pinto, respectively. Each vehicle had two Part 572 test dummies (50 percentile) seated in the front seat. The dummies in the Pinto were instrumented according to FMVSS 208 and were unrestrained. In the Chevelle the dummies were uninstrumented and were restrained with seat belts.

The Chevelle was equipped with automatic transmission, power steering and power brakes. The Pinto had manual transmission, steering and standard brakes. The accident was staged with both transmissions in drive position, brakes off and the engine not running. During the collision no steering control inputs or vehicle braking was applied. The roadway was dry with skid resistance value of 87.

Approximately one car length before impact the vehicle tow cable was released and the vehicle guide rail was terminated. At this point in time and during the collision both vehicles are free bodies with no constraints except the normal collision forces and reactions encountered in this type of car-to-car collision. During the collision event no observed tow cable or instrumentation cable interference with the moving vehicles was noted.

Because the extensive compartment intrusion by the Chevelle major roof deformation occurred on the Pinto caused the roof mounted cameras to change orientation, thereby reducing onboard camera coverage of the dummy kinematics.

Left Front	850 lbs.		Left Rear	860 lbs.
Right Front	780 lbs.		Right Rear	770 lbs.
Total Front	1630 lbs.		Total Rear	1630 lbs.

Total Weight = 1630 lbs. + 1630 lbs. = 3260 lbs.

Wheel Base 93.5 in.

Cg_{FW} = $\frac{1630 \text{ lbs.}}{3260 \text{ lbs.}}$ 93.5 in. = 46.75 in.

DATA CAMERA LOG

PROJECT - RICSAC

TEST NO. 2
DATE: November 18, 1977

CAMERA NO.	LOCATION	TYPE	LENS (mm)	SPEED (fps)
2	NORTHWEST	PHOTOSONIC	35 MM	400
3	NORTH	PHOTOSONIC	50 MM	550
4	NORTHEAST	PHOTOSONIC	25 MM	900
5	TOWER 45	PHOTOSONIC	13 MM	400
6	TOWER CLOSE	PHOTOSONIC	13 MM	350
7	TOWER WIDE	PHOTOSONIC	8 MM	425
8	O. B. ROOF DRIVER	STALEX	8 MM	1400
9	O. B. ROOF PASS.	STALEX	8 MM	1500
10	O. B. DOOR	STALEX	8 MM	1300

NOTE: 1. CAMERAS ARE LISTED ACCORDING TO SPLICING SEQUENCE OF FILM

2. REAL TIME MOVIE FILM COVERAGE OF PRE- AND POST-CRASH AND CRASH EVENT ARE SPLICED AT START AND END OF FILM (24 fps).

3. FOR CAMERA LOCATIONS AND DISTANCE TO SUBJECT SEE FIGURE

TEST NO. 3 PROJECT Staged Car-to-Car Collision

DATE 4/18/78 TIME 13:45 TEMP. 51°F

TEST CONDITION Rear Oblique Offset (26 inch Offset) at 10°

VEHICLE NO. 1 1974 Ford Torino

VEHICLE NO. 2 1974 Ford Pinto

	VEH. NO. 1	VEH. NO. 2
TEST WEIGHT (lbs)	4980	3140
IMPACT ANGLE (deg)*	0	0
IMPACT VELOCITY (mph)**	21.23	0
MAX. CRUSH (in)	2.2"	6.7"
MAX. INTRUSION (in)	None	None

DUMMIES	VEH. NO. 1	VEH. NO. 2
TYPE	Part 572	Part 572
LOCATION	Driver (LF) Passenger (RF)	Driver (LF) Passenger (RF)
RESTRAINT	3-Point Restraint System (Uninstrumented)	(Instrumentation)

NUMBER OF DATA CHANNELS 64
NUMBER OF HIGH SPEED CAMERAS 9

*WITH RESPECT TO TOW TRACK CENTERLINE

**SPEED TRAP MEASUREMENT (±0.5% ACCURACY)

TEAM	YEAR	MONTH	DAY	SEQUENCE
	8	04	18	

V

TABLE 9-1

TEST NO. 3 - CAR NO. 1

VEHICLE DATA

Vehicle data not collected. Reason? _____

Vehicle No. 1

14-15 No. of VIN Characters 11

16-22 VIN (Left Justify, Omit Production Numbers) 4H27023

23-27 Make/Model (CPIR Code) FORD/TAURUS 4dr. 12101

28-32 Mileage (Odometer Reading) 99998 = 99998 mi. or more 65974.

99999 = Unknown

33-34 Model Year 74

35-36 BODY STYLE

Automobiles		Trucks		Other	
Passenger Car	(01)	Van - Passenger	05	School Bus	11
Stationwagon	02	- Cargo	06	Other Bus	12
Convertible	03	Multi-Purpose	07	Motorcycle	13
Car, pickup body (e.g., El Camino, Ranchero, etc.)	04	Pickup	08	Other Body Style	98
		Straight Truck	09	Unknown	99
		Tractor-Trailer	10		

37-39 VEHICLE WEIGHT

Curb 4,000

40-42 Occupant and Cargo Only ___,00

43 TOWING ANOTHER VEHICLE

Yes 1

No (2)

Unknown 9

VEHICLE DAMAGE

	Object Contacted	CDC						Veh. No.	Impact No.
44-54 (1)	01	12	F	Z	E	W	1	2	1
55-65 (2)									
(3)									
(4)									

(1) = Highest Severity (Estimated ΔV)

66 VEHICLE TOWED FROM SCENE

Yes (1)

No 2

Unknown 9

67 SOURCE OF VEHICLE DATA

Inspection at Repair or Tow Facility (1)

Inspection at Person's Home 2

Inspection at Scene 3

Not Inspected (Photos or Repair Data) 4

Not Inspected. Reason. _____ 5

Unknown 9

68 VEHICLE INSPECTION

Not Inspected 0

Inspected on First Visit (1)

Actual Number of Locations Visited (Including Follow-Ups to Same Location) 2 3 4 5 6 7

8 or More 8

Unknown 9

69 APPLICABLE VEHICLE

Yes (1)

No 2

NOTE: COLUMN NUMBERS FROM THE SUMMARY VEHICLE DATA FORM ARE LISTED ON THE LEFT IN THIS FORM TO SIMPLIFY TRANSFER OF DATA.

CAR NO. 2 - 1974 FORD PINTO - TEST NO. 3

TABLE 9-5

VEHICLE TEST WEIGHTS - TEST NO. 3

BULLET VEHICLE

CAR 1 - 1974 FORD TORINO

Left Front	1310 lbs.		Left Rear	1170 lbs.
Right Front	1310 lbs.		Right Rear	1190 lbs.
Total Front	2620 lbs.		Total Rear	2360 lbs.

Total Weight = 2620 lbs. + 2360 lbs. = 4980 lbs.

Wheel Base 117.5 in.

Cg_{FW} = $\frac{2360 \text{ lbs.}}{4980 \text{ lbs.}}$ 117.5 in. = 55.68 in.

TARGET VEHICLE

CAR 2 - 1974 FORD PINTO

Left Front	960 lbs.		Left Rear	620 lbs.
Right Front	930 lbs.		Right Rear	630 lbs.
Total Front	1890 lbs.		Total Rear	1250 lbs.

Total Weight = 1890 lbs. + 1250 lbs. = 3140 lbs.

Wheel Base 94 in.

Cg_{FW} = $\frac{1250 \text{ lbs.}}{3140 \text{ lbs.}}$ 94 in. = 37.42 in.

RICSAC STAGED COLLISION

FRONT-TO-REAR
OBLIQUE - OFFSET

TORINO/PINTO

VELOCITY 38.7 MPH

10.0 RICSAC STAGED COLLISION - TEST NO. 4

EXPERIMENTAL RESULTS

Test Description

This staged collision involved a 1974 Ford Torino (V-1) striking the rear of a stationary 1974 Pinto (V-2) at an oblique 10 degree angle with a 26 inch offset as shown in Figure 10-1. The impact velocity was 38.7 mph. The vehicle test weights were 4980 and 3190 pounds for the Torino and Pinto, respectively. Each vehicle had two Part 572 test dummies (50 percentile) seated in the front seat. The dummies in the Pinto were instrumented according to FMVSS 208 and were unrestrained. In the Torino the dummies were uninstrumented and were restrained with seat belts.

The Torino was equipped with automatic transmission, power steering and power brakes. The Pinto had manual transmission, steering and standard brakes. The accident was staged with both transmissions in drive position, brakes off and the engines not running. During the collision no steering control inputs or vehicle braking was applied. The roadway was dry with skid resistance value of 87.

Approximately one car length before impact the vehicle tow cable was released and the vehicle guide rail was terminated. At this point in time and during the collision both vehicles are free bodies with no constraints except the normal collision forces and reactions encountered in this type of car-to-car collision. During the collision event no observed tow cable or instrumentation cable interference with the moving vehicles was noted.

TEST NO. 5

RICSAC STAGED COLLISION

FRONT-TO-REAR
OBLIQUE - OFFSET

TORINO/HONDA

VELOCITY 39.7 MPH

11.0 RICSAC STAGED COLLISION - TEST NO. 5

EXPERIMENTAL RESULTS

Test Description

This staged collision involved a 1974 Ford Torino (V-1) striking the rear of a stationary 1975 Honda Civic (V-2) at an oblique 10 degree angle with a 26 inch offset as shown in Figure11-1. The impact velocity was 39.7 mph. The vehicle test weights were 4600 and 2530 pounds for the Torino and Honda, respectively. Each vehicle had two Part 572 test dummies (50th percentile) seated in the front seat. The dummies in the Honda were instrumented according to FMVSS 208 and were unrestrained. In the Torino the dummies were uninstrumented and were restrained with seat belts.

The Torino was equipped with automatic transmission, power steering and power brakes. The Honda had manual transmission, steering and power brakes. The accident was staged with both transmissions in drive position, brakes off and the engines not running. During the collision no steering control inputs or vehicle braking was applied. The roadway was dry with skid resistance value of 87.

Approximately one car length before impact the vehicle tow cable was released and the vehicle guide rail was terminated. At this point in time and during the collision both vehicles are free bodies with no constraints except the normal collision forces and reactions encountered in this type of car-to-car collision. During the collision event no observed tow cable or instrumentation cable interference with the moving vehicles was noted.
